## Series 2: Non-contiguous memory management (solution)

## Exercise 1

I)
a)

1) Size of the logical address space (virtual memory space) is:
$2^{24}=16 \mathrm{MB}$ (address on 24 bits therefore the number of combinations or addresses $=2^{24}$ )
2) Offset $=9$ bits (since $2^{9}=512$ the size of a page, so 9 bits are needed to address the 512 slots)
3) $24-9=15$ bits (logical address $=[p$, offset $]$, offset $=9$, then $p=24-9=15$ bits)
4) 20 bits ( $\mathrm{M} . \mathrm{M}$ size $=1 \mathrm{MB}=2^{20}$ bits So the number of bits for addressing this space $2^{20}$ is 20 bits )
5) $20-9=11$ bits (since total bits for a physical address $=20$ then offset $=9$ So $20-9=11$ bits for the frame)
6) $2^{15}=32 \mathrm{~KB}$ (the number of bits to address the pages is 15 then the number of all page addresses $=2^{15}$ which represents the number of elements in the page table $=$ the entries of Page Table)
b) Yes. The program needs 2000 bytes of data (vector) and 1024 bytes of code, so a total of 3024 bytes in memory.
The number of occupied pages: [3024 / 512] $=6$ pages. In the last page, there remain $512-464=48$ free bytes $(464=3024-(512 * 5))$, which causes an internal fragmentation.
II) $32 / 4=8$ bits (The format PT1(8bits) PT2(8bits) PT3(8bits) offset(8bits)

The number of tables: $1+256+(256 * 256)$.
The number of entries: 256

## Exercise 2

Program size=460 Byte
Page size=100 Byte $\quad \rightarrow$ program size with pages= 5 pages
Main Memory size= 200 Byte $\rightarrow$ M.M frames number $=2$ frames

> Waste calculation formula: page size- (pgm size mod page size)

## Number of wasted space $\mathbf{= 1 0 0} \mathbf{- m o d}(460 / 100)=40$ Byte (internal fragmentation at last page)

The reference chain: 101110417073309185245246434458364 corresponding to the following page numbers: 001103122443
NB: to find the number of the corresponding page, you have to make the integer division of the reference number by the size of the page, for example:
For the reference 10: 10/100=0
A) FIFO

|  | 0 | 0 | 1 | 1 | 0 | 3 | 1 | 2 | 2 | 4 | 4 | 3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Frame 0 | 0 | 0 | 0 | 0 | 0 | 3 | 3 | 3 | 3 | 4 | 4 | 4 |
| Frame 1 |  |  | 1 | 1 | 1 | 1 | 1 | 2 | 2 | 2 | 2 | 3 |

Number of page fault is: 6
Page fault rate $=6 / 12 * 100=50 \%$

## B) LRU

|  | 0 | 0 | 1 | 1 | 0 | 3 | 1 | 2 | 2 | 4 | 4 | 3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Frame 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 4 | 4 | 4 |
| Frame 1 |  |  | 1 | 1 | 1 | 3 | 3 | 2 | 2 | 2 | 2 | 3 |

Number of page fault is $=7$
Page fault rate $=7 / 12 * 100=58 \%$

## C) OPTIMAL

|  | 0 | 0 | 1 | 1 | 0 | 3 | 1 | 2 | 2 | 4 | 4 | 3 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Frame 0 | 0 | 0 | 0 | 0 | 0 | 3 | 3 | 3 | 3 | 3 | 3 | 3 |
| Frame 1 |  |  | 1 | 1 | 1 | 1 | 1 | 2 | 2 | 4 | 4 | 4 |

Number of page fault is $=5$
Page fault rate $=5 / 12 * 100=42 \%$

## Exercise 3

## 1 and 2)

-Several algorithms have been proposed:
-Counter method;
-Stack method;
-Mask method

## 1) Counter (Index) method:

Let capacity be the number of pages that memory can hold. Let set be the current set of pages in memory.

1- Start traversing the pages.
i) If set holds less pages than capacity.
a) Insert page into the set one by one until the size of set reaches capacity or all page requests are processed.
b) Simultaneously maintain the recent occurred index of each page in a map called indexes.
c) Increment page fault
ii) Else

If current page is present in set, do nothing. Else
a) Find the page in the set that was least recently used. We find it using index array. We basically need to replace the page with minimum index.
b) Replace the found page with current page.
c) Increment page faults.
d) Update index of current page.
2. Return page faults.

## 2. Mask method

It is an implementation method of the LRU replacement algorithm according to the mask method.

1. Each page is associated with a byte.
2. The initial value of the mask is one byte (00000000). The most significant bit is set to 1 each time this page is used.
3. At each period ( N ms ), a right shift is made of the byte associated with each page.
4. The victim page is the page with the lowest mask value when the algorithm is launched.
```
LRU algorithm;
Var found: boolean;
Min: integer;
Min}\leftarrow\mathrm{ byte-min(number-page-load-mm);
Found}\leftarrow\mathrm{ unique-test(min);
If (found) Then {page is unique}
    Victim-num <Selection(min,list-page-load);
Else {page is not unique}
Victim-num < Selection (min,list-page-load, FIFO);
Finish;
```

3) 

| Stack method | Counter method | Mask method |
| :--- | :--- | :--- |
| It is difficult to manage | it is easy to update | it is easy but requires a shift <br> (update) |
| Stack size increases | the number of counters increases with <br> the size of the central memory | by increasing the size of the <br> main memory we will <br> increase the number of the <br> required bytes |

## Exercise 4

| Access | Segment | Page | Offset | Result |
| :--- | :---: | :---: | :---: | :---: |
| 1. Load data | 0 | 1 | 1 | 6145 |
| 2. Load data | 1 | 1 | 10 | 10 |
| 3. Load data | 3 | 3 | 2047 | Page Fault |
| 4. Save data | 0 | 1 | 4 | Protection fault |
| 5. Data storage | 3 | 1 | 2 | 2050 |
| 6. Save data | 3 | 0 | 14 | 28686 |
| 7. Jump to the address | 1 | 3 | 100 | 16484 |
| 8. Load data | 0 | 2 | 50 | Page Fault |
| 9. Read data | 2 | 0 | 5 | Page table fault |
| 10. Jump to the address | 3 | 0 | 60 | Protection Fault |

The details:
We have the page size $=2 \mathrm{~kb}=2 * 1024=2048 \mathrm{~B}$
Physical address= frame* page size + offset
The access rights must be checked for each case.

1) Access: Load data with: segment=0, page=1 and d=1

From the segment table: the actual page (box) $=3$
So the physical address $=3 * 2048+1=6145$
2) Access: Load data with: segment=1, page=1 and d=10

From segment table: actual page (frame)=0
So the physical address $=0 * 2048+10=10$
3) Access: Load data with: segment=3, page=3 and d=2047

From segment table: real page (frame)=virtual page is on disk
So: page fault
4) Access: save data with: segment=0 or access is read-only $=>$ protection fault
5) ) Access: data storage with: segment=3, page=1 and d=2

From the segment table: the actual page (box)=1
So the physical address=1*2048+2=2050
6) ) Access: save data with: segment=3, page=0 and d=14

From the segment table: the actual page (box)=14
So the physical address $=14 * 2048+14=28686$
7) ) Access: Jump to the address with: segment=1, page=3 and d=100

From the segment table: the actual page (box) $=8$
So the physical address $=8 * 2048+100=16484$
8) ) Access: Load data with: segment $=0$, page $=2$ and $d=50$

From the segment table: the actual page (frame)=on disk
So: Page Fault
9) ) Access: Read data with: segment=2, page=0 and d=5

From the segment table: the page table is not in MC
So: Page table fault
10) ) Access: Jump to the address with: segment=3, page $=0$ and $d=60$

From the segment table: access is read and write only
So: Protection fault

## Exercise 5

a) The translation of a logical address ( $s, p, d$ ) to a physical address:

| Segments | Pages | Cadres |
| :---: | :---: | :---: |
| S1 | 2 | 2 |
|  | 3 | 0 |
| S2 | 2 | 9 |
| S3 | 1 | 12 |

Page size $=4 \mathrm{~kb}=1024^{*} 4=4096$ byte
logical@: $8212=2 * 4096+20$
SO :

1. segment $=$ S1 (The third page is in segment 1)
2. the page number in the segment $=3$
3. Offset in the page $=20$ (the rest)
$\mathrm{S}=1-\mathrm{P}=3$ - Offset=20
4. frame=0 (from array)
5. the displacement in the frame $=20$ (the same displacement as the logical address)

C=0 - offset=20
6. The physical address is therefore 20 in decimal (since the frame number is 0 ). The physical address is expressed in 16 bits (physical space $=64 \mathrm{kB}=2^{16}$ ), including 4 bits for the frame number and 12 bits for the displacement in the frame ( $4 \mathrm{kB}=2^{12}=2^{10} * 2^{2}$ ), which gives us in binary .
$C=0000$ and Offset= 000000010100
